

ESTIMATING THE DIFFICULTY OF BREAKING LATTICE-BASED CRYPTOGRAPHY

WITH A FOCUS ON LWE

Martin R. Albrecht

2022: Royal Holloway, University of London, 2023: King's College London & SandboxAQ

THE PLAN

- Introduce estimating the cost of solving LWE-based schemes
 - strategies (primal and dual lattice attacks)
 - lattice reduction
 - finding short vectors
 - quantum considerations
 - binary secrets
- Introduce usage of "lattice estimator" along the way
 - highlight limitations¹

<https://github.com/malb/lattice-estimator/>

¹Most of what I know about running open-source projects, I learned from William Stein who responded with "Easy, implement it and send us a patch!" when asked "How do I do . . . in SageMath?"

EXAMPLE

```
_ = LWE.estimate.rough(Kyber768)
```

```
usvp                :: rop:  $\approx 2^{182.2}$ , red:  $\approx 2^{182.2}$ ,  $\delta$ : 1.002902,  $\beta$ : 624, d: 1427, tag: usvp  
dual_hybrid         :: rop:  $\approx 2^{184.3}$ , mem:  $\approx 2^{180.8}$ , m: 705,  $\beta$ : 630, d: 1451,  $\alpha$ : 1,  $\zeta$ : 22, tag: dual_hybrid
```

```
_ = LWE.estimate(Kyber768)
```

```
arora-gb            :: rop:  $\approx 2^{\infty}$ , dreg: 94, mem:  $\approx 2^{513.9}$ , t: 2, m:  $\approx 2^{\infty}$ , ...  
bkw                 :: rop:  $\approx 2^{238.3}$ , m:  $\approx 2^{225.5}$ , mem:  $\approx 2^{226.5}$ , b: 19, t1: 1, t2: 17,  $\ell$ : 18, ...  
usvp                :: rop:  $\approx 2^{204.9}$ , red:  $\approx 2^{204.9}$ ,  $\delta$ : 1.002902,  $\beta$ : 624, d: 1427, tag: usvp  
bdd                 :: rop:  $\approx 2^{201.0}$ , red:  $\approx 2^{200.0}$ , svp:  $\approx 2^{200.0}$ ,  $\beta$ : 606,  $\eta$ : 641, d: 1425, tag: bdd  
bdd_hybrid          :: rop:  $\approx 2^{201.0}$ , red:  $\approx 2^{200.0}$ , svp:  $\approx 2^{200.0}$ ,  $\beta$ : 606,  $\eta$ : 641, ...  
bdd_mitm_hybrid     :: rop:  $\approx 2^{356.7}$ , red:  $\approx 2^{355.8}$ , svp:  $\approx 2^{355.6}$ ,  $\beta$ : 623,  $\eta$ : 2,  $\zeta$ : 189, ...  
dual                :: rop:  $\approx 2^{214.2}$ , mem:  $\approx 2^{133.4}$ , m: 723,  $\beta$ : 653, d: 1491,  $\alpha$ : 1, tag: dual  
dual_hybrid         :: rop:  $\approx 2^{206.4}$ , mem:  $\approx 2^{201.9}$ , m: 701,  $\beta$ : 625, d: 1437,  $\alpha$ : 1,  $\zeta$ : 32, tag: dual_hybrid
```

COMPUTATIONAL PROBLEMS

LEARNING WITH ERRORS

Given (\mathbf{A}, \mathbf{c}) , find \mathbf{s} when

$$\begin{pmatrix} \mathbf{c} \end{pmatrix} \equiv \begin{pmatrix} \leftarrow n \rightarrow \\ \mathbf{A} \end{pmatrix} \cdot \begin{pmatrix} \mathbf{s} \end{pmatrix} + \begin{pmatrix} \mathbf{e} \end{pmatrix} \pmod{q}$$

for $\mathbf{c} \in \mathbb{Z}_q^m$, $\mathbf{A} \in \mathbb{Z}_q^{m \times n}$, and $\mathbf{s} \in \mathbb{Z}^n$ and $\mathbf{e} \in \mathbb{Z}^m$ having small entries.

LEARNING WITH ERRORS

Given (\mathbf{A}, \mathbf{c}) , find \mathbf{s} when

$$\begin{pmatrix} \mathbf{c} \end{pmatrix} \equiv \begin{pmatrix} \leftarrow n \rightarrow \\ \mathbf{A} \end{pmatrix} \cdot \begin{pmatrix} \mathbf{s} \end{pmatrix} + \begin{pmatrix} \mathbf{e} \end{pmatrix} \pmod{q}$$

for $\mathbf{c} \in \mathbb{Z}_q^m$, $\mathbf{A} \in \mathbb{Z}_q^{m \times n}$, and $\mathbf{s} \in \mathbb{Z}^n$ and $\mathbf{e} \in \mathbb{Z}^m$ having small entries.

"HAVING SMALL ENTRIES"

Discrete Gaussian the classic, annoying to sample from; \rightarrow

Binomial $\sum_{0 \leq i < \eta} (b_i - b_{\eta+i}) \mid b_j \leftarrow \{0, 1\}$

Small Uniform $\leftarrow [a, \dots, b] \mid a, b \in \mathbb{N}$

```
from estimator import *  
ND.DiscreteGaussian(stddev=2), ND.CenteredBinomial(eta=8), ND.Uniform(-3, 3)
```

$(D(\sigma=2.00), D(\sigma=2.00), D(\sigma=2.00))$

- Literature assumes these all behave essentially the same under attacks
- No loss in security if secret \mathbf{s} and error \mathbf{e} have same distribution [ACPS09]

```
Kyber768 = LWEParameters(  
    n=3 * 256,  
    q=3329,  
    Xs=ND.CenteredBinomial(2),  
    Xe=ND.CenteredBinomial(2),  
    m=3 * 256,  
    tag="Kyber 768",  
)
```

Q: "How do I do NTRU?"

A: "Easy, implement it and send us a patch."

We do not offer `NTRUParameters`, but you can hack it in using `LWEParameters`

See <https://github.com/WvanWoerden/NTRUFatigue> (this is "on the road map")

APPROACHES

UNIQUE SVP/BDD: TRANSLATION

We can reformulate $\mathbf{c} - \mathbf{A} \cdot \mathbf{s} \equiv \mathbf{e} \pmod{q}$ over the Integers as:

$$\begin{pmatrix} q\mathbf{I} & -\mathbf{A} \\ 0 & \mathbf{I} \end{pmatrix} \cdot \begin{pmatrix} * \\ \mathbf{s} \end{pmatrix} + \begin{pmatrix} \mathbf{c} \\ 0 \end{pmatrix} = \begin{pmatrix} \mathbf{e} \\ \mathbf{s} \end{pmatrix}$$

Alternatively:

$$\mathbf{B} = \begin{pmatrix} q\mathbf{I} & -\mathbf{A} & \mathbf{c} \\ 0 & \mathbf{I} & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \mathbf{B} \cdot \begin{pmatrix} * \\ \mathbf{s} \\ 1 \end{pmatrix} = \begin{pmatrix} \mathbf{e} \\ \mathbf{s} \\ 1 \end{pmatrix}$$

In other words, there exists an integer-linear combination of the columns of \mathbf{B} that produces a vector with “unusually” small entries \rightarrow a unique shortest vector.

UNIQUE SVP: COMPUTATIONAL PROBLEM

Unique Shortest Vector Problem for q -ary Lattices

Find a unique shortest vector amongst the integer combinations of the columns of:

$$\mathbf{B} = \begin{pmatrix} q\mathbf{I} & -\mathbf{A} & \mathbf{c} \\ 0 & \mathbf{I} & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

where $\mathbf{B} \in \mathbb{Z}^{d \times d}$.

Decision Variant

Decide if \mathbf{B} has an unusually short vector.

APPROX SVP/SIS: TRANSLATION

- Consider $\mathbf{c} \equiv \mathbf{A} \cdot \mathbf{s} + \mathbf{e} \bmod q$ with both \mathbf{s} and \mathbf{e} short or \mathbf{c} uniform.
- Let \mathbf{u}_i be short vectors such that $\mathbf{v}_i^T := \mathbf{u}_i^T \cdot \mathbf{A} \bmod q$ is also short.
- Compare:
 - $\mathbf{u}_i^T \cdot \mathbf{c} \equiv \mathbf{u}_i^T \cdot \mathbf{A} \cdot \mathbf{s} + \mathbf{u}_i^T \cdot \mathbf{e} \equiv \mathbf{v}_i^T \cdot \mathbf{s} + \mathbf{u}_i^T \cdot \mathbf{e}$ which is somewhat short
 - $\mathbf{u}_i^T \cdot \mathbf{c}$ which is uniform
- The shorter $(\mathbf{u}_i, \mathbf{v}_i)$ the fewer samples of $\mathbf{u}_i^T \cdot \mathbf{c}$ we need to consider
- Note

$$\begin{pmatrix} q\mathbf{I} & \mathbf{A}^T \\ 0 & \mathbf{I} \end{pmatrix} \cdot \begin{pmatrix} * \\ \mathbf{u}_i \end{pmatrix} = \begin{pmatrix} \mathbf{v}_i \\ \mathbf{u}_i \end{pmatrix}$$

APPROX SVP: COMPUTATIONAL PROBLEM

Short Vectors Problem for q -ary Lattices

Find vectors $(\mathbf{u}_i, \mathbf{v}_i)$ of norm $\|(\mathbf{u}_i, \mathbf{v}_i)\| \leq \beta$ amongst the integer combinations of the columns of:

$$\mathbf{B} = \begin{pmatrix} q\mathbf{I} & \mathbf{A}^T \\ 0 & \mathbf{I} \end{pmatrix}$$

where $\mathbf{B} \in \mathbb{Z}^{d \times d}$.

Search Variant

Can extend this distinguishing attack to recover \mathbf{s} : guess a component and run the distinguisher

Both approaches can be augmented with a combinatorial step

- guess parts of the secret and run the lattice attack on a smaller dimensional lattice
- due to linearity costs are additive not multiplicative, i.e.

$$\approx T_{guess} + T_{lattice}$$

"For example, in [AGVW17, Table 1], they validate the 2016 estimate in the case of $n = 110$, $\log(q) = 11$, where their attack requires blocksize 78. In our experiments attacking LWE instances with binary secrets, we successfully attack the same parameters with the same error width using blocksize 35 (see Table 2) with the dimension as predicted in the 2008 estimate. In this case the discrepancy is most likely due to the secret distribution: binary instead of uniform." [CCLS20]

"Second, their methodology does not take into account the norm of their embedded shortest vector. In their experiments they compare $\text{LWE}_{n,q,\chi,m}$ instances where χ is swapped between several distributions with different variances. [... This] does not mean that Gaussian secrets offer 'greater security levels' than binary or ternary secrets, but rather that when fixing n, q, m , the larger the secret variance, the harder the instance." [PV21]

BINARY SECRETS: REDUCTIONS

Theorem (informal, [BD20])

Assume that decision LWE with dimension k , modulus q and Gaussian noise parameter γ is hard. Let \mathcal{S} be a distribution over \mathbb{Z}_q^n with $\nu_{\sigma_1}(\mathcal{S}) \geq k \log(q) + \omega(\log \lambda)$ for some parameter σ_1 and $\nu_{\sigma_1}(\mathcal{S}) := \tilde{H}_\infty(\mathbf{s} \mid \mathbf{s} + \mathbf{e})$ where $\mathbf{s} \leftarrow \mathcal{S}$ and \mathbf{e} is sampled from a discrete Gaussian with width σ_1 . Then Entropic LWE with secret distribution \mathcal{S} and Gaussian noise parameter $\sigma \approx \sigma_1 \cdot \gamma \cdot \sqrt{m}$ is hard.

Personal Claim (Hot Take Alarm)

This roughly implies that binary secret LWE in dimension $n \log q$ is hard if regular LWE in dimension n is hard. I claim we should be able to strengthen this to $n \log \sigma$, which makes a big difference for FHE parameters, where σ is often a small constant. No known attack comes close to mandating $n \log q$.

"Moreover, we also show how the previous algorithm can be used to solve the BinaryLWE problem with n samples in subexponential time $2^{(\ln 2/2 + o(1))n / \log \log n}$ " [KF15].

Note

We don't cover these in the estimator (yet).

ESTIMATOR (PRIMAL)

plain uSVP

```
LWE.primal_usvp(Kyber768)
```

rop: $\approx 2^{204.9}$, red: $\approx 2^{204.9}$, δ : 1.002902, β : 624, d: 1427, tag: usvp

plain BDD (minor parameter relaxation compared to uSVP)

```
LWE.primal_bdd(Kyber768)
```

rop: $\approx 2^{201.0}$, red: $\approx 2^{200.0}$, svp: $\approx 2^{200.0}$, β : 606, η : 641, d: 1425, tag: bdd

BDD + combinatorics

```
LWE.primal_hybrid(Kyber768)
```

rop: $\approx 2^{356.7}$, red: $\approx 2^{355.8}$, svp: $\approx 2^{355.6}$, β : 623, η : 2, ζ : 189, $|S|$: $\approx 2^{367.1}$, d: 1278, ...

ESTIMATOR (DUAL)

plain SIS

```
LWE.dual(Kyber768)
```

rop: $\approx 2^{214.2}$, mem: $\approx 2^{133.4}$, m: 723, β : 653, d: 1491, α : 1, tag: dual

SIS + combinatorics

```
LWE.dual_hybrid(Kyber768)
```

rop: $\approx 2^{206.4}$, mem: $\approx 2^{201.9}$, m: 701, β : 625, d: 1437, α : 1, ζ : 32, tag: dual_hybrid

Q: "How do I use the estimates from [MAT22]?"

A: "Easy, I have implemented it [AS22] and just need to submit the patch."²

²Stuff gets implemented in the estimator when someone needs it for a project; ideally, attack authors would submit estimates for their attacks.

LATTICE REDUCTION

LATTICE VOLUME

The volume of a lattice is the volume of its fundamental parallelepiped.

Picture Credit: Joop van der Pol

GAUSSIAN HEURISTIC

- The Gaussian heuristic predicts that the number $|\Lambda \cap \mathcal{B}|$ of lattice points inside a measurable body $\mathcal{B} \subset \mathbb{R}^d$ is approximately equal to $\text{Vol}(\mathcal{B}) / \text{Vol}(\Lambda)$.
- Applied to Euclidean d -balls, this means that a shortest vector in a lattice has expected norm

$$\lambda_1(\Lambda) \approx \text{GH}(d) \cdot \text{Vol}(\Lambda)^{1/d} \approx \sqrt{\frac{d}{2\pi e}} \cdot \text{Vol}(\Lambda)^{1/d}.$$

Unusually Shortest Vector

When $\lambda_1(\Lambda) \ll \sqrt{\frac{d}{2\pi e}} \cdot \text{Vol}(\Lambda)^{1/d}$.

LENGTH OF GRAM–SCHMIDT VECTORS

It will be useful to consider the lengths of the Gram–Schmidt vectors.

The vector \mathbf{b}_i^* is the orthogonal projection of \mathbf{b}_i to the space spanned by the vectors $\mathbf{b}_0, \dots, \mathbf{b}_{i-1}$.

Informally, this means taking out the contributions in the directions of previous vectors $\mathbf{b}_0, \dots, \mathbf{b}_{i-1}$.

We have $\text{Vol}(\Lambda) = \prod_{i=0}^{d-1} \|\mathbf{b}_i^*\|$.

LENGTH OF GRAM–SCHMIDT VECTORS

It will be useful to consider the lengths of the Gram–Schmidt vectors.

The vector \mathbf{b}_i^* is the orthogonal projection of \mathbf{b}_i to the space spanned by the vectors $\mathbf{b}_0, \dots, \mathbf{b}_{i-1}$.

Informally, this means taking out the contributions in the directions of previous vectors $\mathbf{b}_0, \dots, \mathbf{b}_{i-1}$.

We have $\text{Vol}(\Lambda) = \prod_{i=0}^{d-1} \|\mathbf{b}_i^*\|$.

EXAMPLE

```
A = IntegerMatrix.random(120, "qary", k=60, bits=20)[::-1]
M = GSO.Mat(A, update=True)
line([(i, log(r_, 2)/2) for i, r_ in enumerate(M.r())], **plot_kwds)
```

EXAMPLE - LLL

```
A = LLL.reduction(A)
M = GSO.Mat(A, update=True)
line([(i, log(r_, 2)/2) for i, r_ in enumerate(M.r())], **plot_kwds)
```

Geometric Series Assumption: The shape after lattice reduction is a line with a flatter slope as lattice reduction gets stronger.³

```

rop: $\approx 2^{204.9}$, red: $\approx 2^{204.9}$, δ : 1.002902, β : 624, d: 1427, tag: usvp

rop: $\approx 2^{209.9}$, red: $\approx 2^{209.9}$, δ : 1.002842, β : 642, d: 1421, tag: usvp

- If τ is the number of tours we do, we run our oracle $\approx \tau \cdot d$ times
- So the cost is roughly $\tau \cdot d \cdot T_{SVP}$.
- We can reduce some of this cost

Tail is cheaper than the head as we decrease the block sizes

Progressive BKZ Run BKZ- β' with $\beta' < \beta$ before running BKZ- β

Skipping blocks We may get away with "skipping" some blocks.

- `LWE.estimate.rough` assumes **one** call to the oracle ("Core-SVP")
- `LWE.estimate` assumes roughly $8 \cdot d$, i.e. $\tau = 8$

Q: "How do I ...?"

SIS "Easy, implement it and send us a patch."⁴

Verify "Easy, check the code and send us patches."

⁴It is on the roadmap, though.

SOLVING SVP

Enumeration

- Search through vectors smaller than a given bound: project down to 1-dim problem, lift to 2-dim problem ...
- Sensitive to the quality of the input basis
- **Time:** $2^{\Theta(\beta \log \beta)}$
- **Memory:** $\text{poly}(\beta)$

Sieving

- Produce new, shorter vectors by considering sums and differences of existing vectors
- Fairly oblivious to the quality of the input basis
- **Time:** $2^{\Theta(\beta)}$
- **Memory:** $2^{\Theta(\beta)}$

FAST ENUMERATION

- Do not exhaust the search space, but focus on a fraction with exponentially small probability of success, repeat exponentially often: speed-up $2^{\Theta(\beta)}$
- Preprocess the basis with BKZ- β' for some $\beta' \leq \beta$ before enumerating.

PRACTICAL PERFORMANCE (SIMULATION)

beta, d = 500, 1000

RC.CheNgu12(beta, d).log(2), RC.ABFKSW20(beta, d).log(2), RC.ABLR21(beta, d).log(2)

(365.668328064860, 316.227302076042, 278.167302076042)

[CN11; ABFKSW20; ABLR21]

SIEVING: KEY IDEA I

SIEVING: KEY IDEA II

SIEVING: KEY IDEA III

SIEVING: BASIC (GAUSS) SIEVE COMPLEXITY

- Assume all vectors have (roughly) the same length
- Normalise to unit sphere $\mathcal{S}^{d-1} := \{\mathbf{x} \in \mathbb{R}^d \mid \|\mathbf{x}\| = 1\}$
- We have $\|\mathbf{v} - \mathbf{w}\| \leq 1$ iff $\langle \mathbf{v}, \mathbf{w} \rangle \geq 1/2 = \cos(\pi/3)$
- The probability that two random $\mathbf{v}, \mathbf{w} \in \mathcal{S}^{d-1}$ satisfy $\langle \mathbf{v}, \mathbf{w} \rangle \geq 1/2$ is

$$= \text{poly}(d) \cdot \left(\frac{4}{3}\right)^{d/2} \approx 2^{0.2075 d + o(d)}$$

- Need $\text{poly}(d) \cdot \left(\frac{4}{3}\right)^{d/2}$ vectors, comparing all pairs costs $\text{poly}(d) \cdot \left(\frac{4}{3}\right)^d \approx 2^{0.4150 d + o(d)}$.

SIEVING: BUCKETS I

SIEVING: BUCKETS II

If \mathbf{v} , \mathbf{c} are somewhat close and \mathbf{w} , \mathbf{c} are somewhat close then perhaps \mathbf{w} , \mathbf{v} are close?

Strategy

- Sort vectors into somewhat loose buckets,
- Do quadratic pairwise comparison only within each bucket.

BGJ Split search space into buckets. **Cost:** $2^{0.311\beta + o(\beta)}$.⁵

BDGL Use codes to decide which bucket to consider. **Cost:** $2^{0.292\beta + o(\beta)}$.⁶

G6K⁷ is a Python/C++ framework for experimenting with sieving algorithms (inside and outside BKZ)

- Does not take the “oracle” view but considers sieves as stateful machines.
- Implements several sieve algorithms
 - Gauss and NV
 - Triple Sieve
 - BGJ1 (BGJ with one level of filtration)
 - BDGL (with one and two block respectively)
- Applies recent tricks and adds new tricks for improving performance of sieving

QUANTUM STUFF

Sieving Given some vector \mathbf{w} and a list of vectors L , apply Grover's algorithm to find $\{\mathbf{v} \in L \text{ s.t. } \|\mathbf{v} \pm \mathbf{w}\| \leq \|\mathbf{w}\|\}$.⁸

Enumeration Apply Montanaro's quantum backtracking algorithm for quadratic speed-up.⁹

⁸Thijs Laarhoven. [Search problems in cryptography: From fingerprinting to lattice sieving](#). PhD thesis. Eindhoven University of Technology, 2015.

⁹Yoshinori Aono, Phong Q. Nguyen, and Yixin Shen. [Quantum Lattice Enumeration and Tweaking Discrete Pruning](#). In: *ASIACRYPT 2018, Part I*. ed. by Thomas Peyrin and Steven Galbraith. Vol. 11272. LNCS. Springer, Heidelberg, Dec. 2018, pp. 405–434. DOI: 10.1007/978-3-030-03326-2_14.

QUANTUM SIEVING

- A quantum sieve needs list of $2^{0.2075\beta}$ vectors before pairwise search with Grover
- Fast sieves use that the search is structured, Grover does unstructured search
 - Quantum Gauss Sieve

$$2^{(0.2075 + \frac{1}{2} 0.2075) \beta + o(\beta)} = 2^{0.311 \beta + o(\beta)} \text{ time, } 2^{0.2075 \beta + o(\beta)} \text{ memory}$$

- Classical BGJ Sieve¹⁰

$$2^{0.311 \beta + o(\beta)} \text{ time, } 2^{0.2075 \beta + o(\beta)} \text{ memory}$$

- Asymptotically fastest sieves have small lists and thus less Grover speed-up potential

¹⁰Anja Becker, Nicolas Gama, and Antoine Joux. *Speeding-up lattice sieving without increasing the memory, using sub-quadratic nearest neighbor search*. Cryptology ePrint Archive, Report 2015/522. <https://eprint.iacr.org/2015/522>. 2015.

IMPLEMENTING QUANTUM ALGORITHMS FOR SVP: SIEVING (UNDERESTIMATES)

Martin R. Albrecht, Vlad Gheorghiu, Eamonn W. Postlethwaite, and John M. Schanck. [Estimating Quantum Speedups for Lattice Sieves](#). In: *ASIACRYPT 2020, Part II*. ed. by Shiho Moriai and Huaxiong Wang. Vol. 12492. LNCS. Springer, Heidelberg, Dec. 2020, pp. 583–613. DOI: [10.1007/978-3-030-64834-3_20](https://doi.org/10.1007/978-3-030-64834-3_20)

QUANTUM ESTIMATES DO NOT SEEM TO MATTER

- The resistance of post-quantum algorithms to quantum computers is routinely, e.g. in the NIST PQC Standardization Process, compared to that of the AES family of block ciphers.
- The state of the art is that AES- λ resists classical attacks of cost $\approx 2^\lambda$ and quantum attacks of cost $\approx 2^{\lambda/2}$, the latter being due to Grover's algorithm.¹¹
- Parameters for post-quantum schemes are chosen such that they resist known classical attacks of cost $\approx 2^\lambda$ and known quantum attacks of cost $\approx 2^{\lambda/2}$ and any algorithm with complexity $\gg 2^{\lambda/2}$ will not affect the claimed security level.

¹¹See [JNRV20] for more detailed cost estimates.

BKW combinatorial technique, relatively efficient for small secrets

- Don't need to worry about this unless secret is unusually small (e.g. ternary) and/or sparse.

Arora-Ge use Gröbner bases, asymptotically efficient , but large constants in the exponent

- Don't need to worry about this unless you are given a lot of samples and have constant size errors
